## 1 Introduction

A very important concept in mathematics is the idea of an *invariant*: An object which does not change under a certain action. In 1872, Felix Klein came up with a then new method of describing geometries with group theory, called the Klein Erlangen program (see [Kle93]). Here, the central idea of a geometry is characterized by its associated symmetry group, the group of transformations which leaves certain objects unchanged, for example: angles. The study of these transformations is called conformal geometry.

Let us discuss the following important example in geometry: Consider all transformations which map lines to lines, id est, such transformations under which the property of being a line is invariant. The fundamental theorem of projective

geometry gives us that these maps are exactly the projective transformations (see [Aud03, Ex V.44, Ex I.51]).

Conversely, we can now just consider projective transformations as our given group of transformations. **Invariant theory asks: What invariants exist?** We can loosely notice a kind of duality between geometries viewed as in the Klein Erlangen program and invariant theory. This discipline of mathematics usually only looks at invariants described with so called regular terms, or more concretely formulated: In invariant theory, we try to find invariant polynomial-like functions.

Staying in our example of considering projective transformations as our given group, a well known example for an invariant is the cross ratio. It is a rational polynomial which takes as its input four collinear points. Is this the only invariant? How can we find other invariants? How big is the ring of all invariants?

*Hilbert's finiteness theorem* states that for regular actions under certain groups, such that are *linearly reductive*, the invariant ring is finitely generated. If we can find these finite generators, we have a grasp of what all invariants look like. Hilbert's first proof for this theorem was non-constructive. It is claimed that this proof was responsible for Gordan's famous quote "Das ist Theologie und nicht Mathematik" (see [DK15, p.42]). The central idea of this proof is the existence of a Reynolds operator.

One of the most important and most common groups is the general linear group  $GL_n$ . This group is linearly reductive and there are multiple ways to see this. Motivated by averaging for finite groups, it is possible to replace the sum by an integral with the Haar-measure, which enables us to construct a  $GL_n$ -invariant inner product. This shows that  $GL_n$  is linearly reductive, since we can get module complements from the inner product. One can also show linear reductivity by the Schur-Weyl-duality: The symmetric group is finite, from which we can therefore see that in any rational  $GL_n$ -representation we can again construct module complements.

Here, we will show that  $GL_n$  is linear reductive in an even different way. For one, we want to show that a Reynolds Operator exists, which already means that  $GL_n$  is linearly reductive. But we want even more than just the existence. What does it help for our motivation to get a grasp of what all (or even just some) invariants look like, if we merely prove the existence of a finite generator set for the invariants? Since this operator projects polynomials to invariant polynomials, if we can find an explicit formula for computing the Reynolds operator applied to a polynomial, we can more easily receive concrete invariants. **This is possible with Cayley's  $\Omega$ -process.** This is the main goal of my work.

I say "more easily" receive invariants, because if we take a polynomial at random and apply the Reynolds Operator, we might very likely just get a constant polynomial, which is not a very interesting invariant, and we also want to know if there are more invariants. Similar to the first proof of Hilbert's finiteness theorem (by Hilbert himself, see [DK15, p.41,42]), we can show that there are certain finitely many polynomials whose images under the Reynolds operator will generate the invariant ring. Although this is not what I will be discussing

in detail in my work, there is in fact an algorithm to compute these certain polynomials. With the help of Cayley's  $\Omega$ -process, we then get a complete algorithm that gives us the generators of the invariant ring.

## 2 Preliminary Work

### 2.1 Notation

In the following,  $K$  is a field of characteristic 0 and  $G$  a linear algebraic group, that is a group which is an affine variety, and whose multiplication and inversion are morphisms of affine varieties.

For us, zero is an element of the natural numbers. Furthermore, for  $n \in \mathbb{N}$  we write  $[n] := \{m \in \mathbb{N} \mid 1 \leq m \leq n\}$ .

For an affine variety  $X$ , we denote by  $K[X]$  the coordinate ring of  $X$ . If  $\{f_i\}_{i \in [r]} \subseteq K[X]$ , we denote by  $K[\{f_i\}_{i \in [r]}]$  the subring of  $K[X]$  generated by  $\{f_i\}_{i \in [r]}$ . For a finite-dimensional vector-space  $V$ , we denote by  $X_i$  the coordinate functions for a given (often a canonical) basis. For a set of functions in the coordinate ring  $F \subseteq K[X]$  we denote by  $Z(F)$  the zero set of  $F$ . For a subset of a ring  $M$ ,  $(M)$  denotes the ideal generated by  $M$ .

### 2.2 Concepts From Algebraic Geometry

#### Proposition 2.1: Rabinowitsch Trick

Let  $V = K^n$  for some  $n \in \mathbb{N}$ . For a polynomial  $p \in K[V] = K[\{X_i\}_{i \in [n]}]$ , the set  $X_p := \{v \in V \mid p(v) \neq 0\}$  has the structure of an affine variety with the coordinate ring  $K[X_p] = K[\{X_i\}_{i \in [n]}, p^{-1}]$ .

(Compare to [Rab30])

*Proof.* The set  $X_p$  is not an algebraic set itself. The trick (the ‘‘Rabinowitsch-trick’’) is ‘‘adding an additional variable  $X_0$ ’’, that means to consider  $X_p$  as a subset of  $K \times V$ . We do this as follows: Consider the algebraic set  $\tilde{X}_p := Z(X_0 \cdot p - 1) \subseteq K \times V$ . We notice that  $\tilde{X}_p = \{(p(v)^{-1}, v) \in K \times V \mid v \in X_p\}$ . This means that  $X_p$  corresponds to  $\tilde{X}_p$  via the bijection  $\Phi: X_p \rightarrow \tilde{X}_p$ ,  $v \mapsto (1/p(v), v)$ . The coordinate ring of  $\tilde{X}_p$  can be written as  $K[\bar{X}_0, \{\bar{X}_i\}_{i \in [n]}]$ , where  $\bar{X}_i = X_i \bmod X_0 \cdot p - 1$ . Let  $x \in X_p$ . We have  $\bar{X}_0(\Phi(v)) = p(x)^{-1}$  and for  $i \in [n]$  we have  $\bar{X}_i(\Phi(x)) = v_i$ . This shows our claim:  $X_p$  has the structure of an affine variety with the coordinate ring  $K[X] = K[\{X_i\}_{i \in [n]}, p^{-1}]$ .  $\square$

#### Example 2.2: The General Linear Group $GL_n$

One of the most important examples is the general linear group  $GL_n$ , which will be an essential theme in my work. By the above proposition this group is an affine variety via  $p = \det$  with the coordinate ring  $K[\{X_{i,j}\}_{i,j \in [n]}, \det^{-1}]$ . This makes  $GL_n$  into a *linear algebraic group*, that is a group which is an affine variety whose group operations of the multiplication and inversion are morphisms of affine varieties: The multiplication is just a polynomial function

in each entry. For the inversion each entry is a fraction of polynomials with det as the quotient, which means that each entry is in  $K[\mathrm{GL}_n]$ .

**Definition 2.3: Algebraic Cohomorphism For Product Spaces**

Let  $m: U_1 \times U_2 \rightarrow W$  be a morphism of affine varieties. The algebraic cohomomorphism  $m^*$  of  $m$  is just the pullback, that is a map of the type  $m^*: K[W] \rightarrow K[U_1 \times U_2]$ . We have  $K[U_1 \times U_2] = K[\{X_k\}_{k \in [r]}, \{Y_l\}_{l \in [s]}]$ , where  $\{X_k\}_{k \in [r]}$  and  $\{Y_l\}_{l \in [s]}$  are generators of  $K[U_1]$  and  $K[U_2]$  respectively. The map

$$K[U_1 \times U_2] \rightarrow K[U_1] \otimes K[U_2]$$

$$\sum_i \lambda_i \prod_j X_j^{d_{i,j}} \prod_k Y_k^{e_{i,k}} \mapsto \sum_i \lambda_i \prod_j X_j^{d_{i,j}} \otimes \prod_k Y_k^{e_{i,k}} \quad (1)$$

is independent of the choice of generators and independent of the representatives and therefore well-defined. This is an isomorphism, and each evaluation of  $K[U_1] \otimes K[U_2]$  corresponds to exactly one element in  $K[U_1 \times U_2]$ , which means that in terms of algebraic geometry, we can view them as equal, in the sense that  $K[U_1] \otimes K[U_2]$  describes the coordinate ring  $K[U_1 \times U_2]$ . We therefore write  $m^*: K[W] \rightarrow K[U_1] \otimes K[U_2]$

**Remark 2.3.1**

One might ask why we use this notation “ $K[U_1] \otimes K[U_2]$ ”. It helps to formalize performing operations only on the “left part” or the “right part”, as we will soon see. This notation is found in [DK15], but other literature such as [Stu08] don’t take this approach. To give a very simple example: If  $G$  is a linear algebraic group and  $m$  is its multiplication, for  $f \in K[Z]|_G$  we would write  $\mathrm{id} \otimes \frac{\partial}{\partial Z_i}(m^*f)$  as in [DK15], whereas [Stu08] would write  $\frac{\partial}{\partial Y_i}(m^*f)$ , often also written as  $\frac{\partial}{\partial Y_i}(f(XY))$ .

## 2.3 Concepts From Invariant Theory

**Definition 2.4: Regular Action, Rational Representation**

Let  $G$  be a linear algebraic group and  $X$  an affine variety. We call an action  $G \times X \rightarrow X$  a **regular action**, if and only if  $\mu$  is a morphism of affine varieties. We say  $G$  **acts regularly on  $X$** , and we also call  $X$  a  **$G$ -variety**.

For a finite-dimensional vector space  $V$ , let  $\mu: G \times V \rightarrow V$  be a representation in the classical sense, that is for all  $g \in G$  we have  $D_\mu(g) := (v \mapsto \mu(g, v)) \in \mathrm{GL}(V)$ . We call  $\mu$  a *rational representation* if and only if it is regular. (See [DK15, p. 31])

**Example 2.4.1**

If  $G$  is a linear algebraic group, then the multiplication  $m: G \times G \rightarrow G$  defines a regular action, meaning that  $G$  itself is a  $G$ -variety.

**Definition 2.5**

If  $\mu: G \times V \rightarrow V$  is a rational representation, we define a rational representation  $\hat{\mu}: G \times V^* \rightarrow V^*$  by  $(\sigma, \varphi) \mapsto \sigma \cdot \varphi := (v \mapsto \varphi(\hat{\mu}(\sigma, v)) = \varphi(\sigma^{-1} \cdot v))$ .

**Definition 2.6: Rational Linear Action**

Let  $V$  be a vector space (not necessarily finite dimensional), and  $\mu : G \times V \longrightarrow V$  an action. We call  $\mu$  a **rational linear action** if and only if there exists a linear map  $\mu' : V \longrightarrow K[G] \otimes V$  such that  $\mu(\sigma, v) = ((\epsilon_\sigma \otimes \text{id}) \circ \mu')(v)$ . (See [DK15, A.1.7])

**Remark 2.6.1**

From the definition, it should immediately be apparent that rational linear actions are linear and regular.

**Definition 2.7**

Let  $\mu : G \times X \longrightarrow X$  be a regular action. We define an action  $\bar{\mu} : G \times K[X] \longrightarrow K[X]$  via  $\bar{\mu}(\sigma, f)(x) := f(\mu(\sigma^{-1}, x))$ , and we write  $\sigma.f(x) := f(\sigma^{-1}.x)$ , where  $\sigma \in G$ ,  $f \in K[X]$  and  $x \in X$ .

This action is obviously regular, but it is also easily shown that it is in fact a rational linear action: If  $\tilde{\mu} : G \times X \longrightarrow X$  is the morphism of affine varieties (it is in fact a right action) defined by  $(\sigma, x) \mapsto \tilde{\mu}(\sigma, x) := \mu(\sigma^{-1}, x)$ , then we can define  $\bar{\mu}' := \tilde{\mu}^*$  with the desired properties.

**Proposition 2.8**

Let  $X$  be an affine  $G$ -variety. If for  $f \in K[X]$  we have  $\bar{\mu}'(f) = \sum_{i=1}^r p_i \otimes g_i$ , then for every  $\sigma \in G$  we have  $\bar{\mu}'(f) = \sum_{i=1}^r \sigma.p_i \otimes \sigma.g_i$ .

*Proof.* Let  $\tau \in G$  and  $x \in X$ . Then

$$\begin{aligned} \sum_{i=1}^r \sigma.p_i \otimes \sigma.g_i(\tau, x) &= \sum_{i=1}^r p_i(\sigma^{-1}\tau) \otimes g_i(\sigma^{-1}.x) \\ &= \sigma^{-1}\tau.f(\sigma^{-1}.x) \\ &= \tau.f(x) = \bar{\mu}'(f)(\tau, x) \end{aligned} \tag{2}$$

□

**Definition 2.9**

Let  $V$  be a finite dimensional vector-space  $\mu : G \times V \longrightarrow V$  a rational representation. We then define an action  $\hat{\mu} : G \times V^* \longrightarrow V^*$ ,  $(\sigma, \varphi) \mapsto \sigma.\varphi := (v \mapsto \varphi(\mu(\sigma^{-1}, v))) = \varphi(\sigma^{-1}.v)$ , which is a rational representation of  $G$ .

**Definition 2.10**

Let  $G$  be a linear algebraic group with the multiplication  $m : G \times G \longrightarrow G$ . For  $\sigma \in G$  and for  $p \in K[G]$  we define  $\sigma.p := (\tau \mapsto p(\tau\sigma))$ .

**Proposition 2.11**

Let  $X$  be an affine variety and  $\mu : G \times X \longrightarrow X$  a regular action. For  $f \in K[X]$ , if we have  $\bar{\mu}'(f) = \sum_{i=1}^r p_i \otimes g_i$  for some  $\{g_i\}_{i \in [r]}$ , then for  $\sigma \in G$  we get  $\bar{\mu}'(\sigma.f) = \sum_{i=1}^r \sigma.p_i \otimes g_i$ .

*Proof.* For  $f \in K[X]$  we have  $\bar{\mu}'(f) = \sum_{i=1}^r p_i \otimes g_i$  for some  $\{g_i\}_{i \in [r]}$ . Now let

$\sigma \in G$ . Then for all  $\tau \in G$  and for all  $x \in X$  we have

$$\begin{aligned}
\bar{\mu}'(\sigma.f)(\tau, x) &= ((\epsilon_\tau \otimes \text{id}) \circ \bar{\mu}')(\sigma.f)(x) \\
&= (\tau.(\sigma.f))(x) \\
&= \sum_{i=1}^r p_i(\tau\sigma)g_i(x) \\
&= \sum_{i=1}^r \sigma \cdot p_i(\tau)g_i(x) = (\sum_{i=1}^r \sigma \cdot p_i \otimes g_i)(\tau, x)
\end{aligned} \tag{3}$$

□

**Definition 2.12: locally finite**

For a vector space  $V$ , we call an action  $\mu: G \times V \longrightarrow V$  **locally finite**, if and only if for every  $v \in V$  there exists a  $G$ -stable finite-dimensional vector space  $U \subseteq V$  such that  $v \in U$ .

**Definition 2.13**

Let  $V$  be a vector-space and  $\mu: G \times V \longrightarrow V$  an action. For  $v \in V$  we define  $V_v := \text{span } G.v$ .

**Remark 2.13.1**

$V_v$  is always a  $G$ -stable subspace of  $V$ . For any  $G$ -stable subspace  $W \subseteq V$  we have  $V_v \subseteq W$ . Therefore, an action  $\mu: G \times V \longrightarrow V$  is locally finite if and only if  $V_v$  is finite-dimensional.

**Proposition 2.14**

Let  $V$  be a vector space.

- (a) If  $\mu: G \times V \longrightarrow V$  is a rational linear action, then the action is locally finite, and every finite-dimensional  $G$ -stable subspace  $W$ ,  $\mu|_{G \times W}$  is a rational representation.
- (b) If  $V$  is a finite-dimensional vector space and  $\mu: G \times V \longrightarrow V$  is a rational representation, then  $\mu$  is also a rational linear action.

*Proof.* See [DK15, A.1.8] and [DK15, 2.2.5, 2.2.6]

(a)

Assume that  $\mu$  is a rational linear action. Let  $v \in V$ . We can write  $\mu'(v) = \sum_{i=1}^l f_i \otimes v_i$ . We then easily see that  $V_v \subseteq \text{span}\{v_i\}_{i=1}^l$ , showing that the action is locally finite. Since  $\mu'$  is linear,  $\mu$  is also linear, therefore we immediately get that  $\mu|_{G \times W}$  is a rational representation.

(b)

Let  $V$  be a finite-dimensional vector-space and  $\mu: G \times V \longrightarrow V$  a rational representation. This means that for all  $\sigma \in G$  we have  $D_\mu(\sigma) \in \text{GL}(V)$ . Let us now choose a basis  $\{v_i\}_{i \in [r]}$  of  $V$ . For all  $\sigma \in G$  there then exist unique  $\{(D_\mu)_{i,j}\}_{i,j \in [r]} \subseteq K$  such that for all  $i \in [r]$  we have  $\mu(\sigma, v_i) = \sum_{k=1}^r (D_\mu)_{i,k} v_k$ . Since the action is regular, we must have  $p_{i,j} := (\mu \mapsto (D_\mu)_{i,k}) \in K[G]$ . We now define  $\mu': V \longrightarrow K[G] \otimes V$  as the linear extension of  $v_i \mapsto \sum_{k=1}^r p_{i,k} \otimes v_k$  where for  $i \in [r]$ . It should be clear that  $\mu'$  satisfies  $\mu(\sigma, v) = ((\epsilon_\sigma \otimes \text{id}) \circ \mu')(v)$  for all  $\sigma \in G$  and  $v \in V$ . This shows that  $\mu$  is a rational linear action. □

**Remark 2.14.1**

This shows that for a finite-dimensional vector space  $V$ , an action is rational if and only if it defines a rational representation. In other words, we have shown that rational representations are exactly defined by rational linear actions on finite-dimensional vector-spaces, which justifies the choice of the names of our definitions.

**Remark 2.14.2**

A rational representation  $\mu: G \times V \mapsto V$  is of the following form:

Consider  $D_\mu: G \mapsto \text{GL}(V)$ . If then  $a_{i,j}: G \rightarrow K$  is the function of the  $(i,j)$ -entry of  $D_\mu$ , then  $a_{i,j} \in K[G]$ .

In fact, it is equivalent to define a representation  $\mu: G \times V \rightarrow V$  ( $V$  finite dimensional) as rational, iff  $D_\mu: G \rightarrow \text{GL}(V)$  is a map of affine varieties.

**Definition 2.15: Invariants**

Let  $G$  act on  $X$  regularly.

$$X^G := \{ x \in X \mid \forall g \in G : g.x = x \} \quad (4)$$

This defines a linear subspace. The given action induces an action  $\bar{\mu}: G \times K[X] \rightarrow K[X]$  as per definition 2.7. The **invariant ring** of the representation is defined as

$$K[X]^G := \{ f \in K[X] \mid \forall g \in G : g.f = f \} \quad (5)$$

As the name implies,  $K[X]^G$  defines a subalgebra of  $K[X]^G$ .

The general theme of my work revolves around the question of whether the invariant ring  $K[X]^G$  is finitely generated.

*Hilbert's finiteness theorem* states that if the group  $G$  is linearly reductive,  $K[V]^G$  is finitely generated. The strict definition of “linearly reductive” is quite tricky, but we will shortly give alternate characterizations.

### 3 Linearly Reductive Groups, The Reynolds Operator And Hilbert's Finiteness Theorem

#### 3.1 The Reynolds Operator And Linearly Reductive Groups

**Definition 3.1: Linearly Reductive Group**

Let  $G$  be a linear algebraic group. We call  $G$  **linearly reductive**, if and only if for any rational representation  $V$ , the spaces  $(V^*)^G$  and  $V^G$  are dual to each other with respect to the canonical pairing  $b: V^* \times V \rightarrow K$ ,  $(\varphi, v) \mapsto \varphi(v)$ , that is  $b|_{(V^*)^G \times V^G}$  is non-degenerate.

**Definition 3.2**

If we have a given action of a group  $G$  on a set  $X$ , we call a map  $A: X \rightarrow Y$   **$G$ -invariant** if and only if we have  $A(\sigma.x) = A(x)$  for all  $\sigma \in G$  and  $x \in X$ .

**Definition 3.3: Reynolds Operator**

Let  $X$  be an affine  $G$ -variety. A  $G$ -invariant linear projection  $R: K[X] \rightarrow K[X]^G$  is called a **Reynolds operator**.

**Definition 3.4**

Assume that  $V$  is a rational representation of  $V$  such that there exists a unique subrepresentation  $W$  of  $V$  such that  $V = V^G \oplus W$ . We define  $R_V: V \rightarrow V^G$  as the linear projection of  $V$  onto  $V^G$  along  $W$ .

**Remark 3.4.1**

$R_V$  is a  $G$ -invariant projection of  $V$  onto  $V^G$ : If for  $v \in V$  we write  $v = u + w$  with  $u \in V^G$  and  $w \in W$ , then for  $\sigma \in G$  we have  $\sigma.v = \sigma.u + \sigma.w = u + \sigma.w$  and  $\sigma.w \in W$ , therefore we have  $R_V(\sigma.v) = u = R_V(v)$ .

**Lemma 3.5**

Assume that  $G$  is a linear algebraic group with the following property: For every rational representation  $V$  of  $G$  there exists a unique subrepresentation  $W$  of  $V$  such that  $V = V^G \oplus W$ , and for this  $W$  we have  $(W^*)^G = \{0\}$ . The following properties hold:

- (a) If  $V$  is a subrepresentation of a rational representation  $V'$  of  $G$ , we have  $R_{V'}|_V = R_V$ .
- (b) If  $V$  is a rational representation of  $G$  and  $R'_V: V \rightarrow Y$  is a  $G$ -invariant linear map with  $V \subseteq Y$  and  $R'_V|_{V^G} = \text{id}_{V^G}$ , we have  $R'_V = R_V$ , id est  $R_V$  is unique with this property<sup>1</sup>
- (c) If  $X$  is an affine  $G$ -variety and  $R: K[X] \rightarrow K[X]^G$  is a Reynolds operator, then for every  $G$ -stable subspace  $V$  of  $K[X]$  we have  $R|_V = R_V$ .
- (d) If  $X$  is an affine  $G$ -variety,  $R: K[X] \rightarrow K[X]^G$  a Reynolds operator and  $W$  is any  $G$ -stable subspace of  $K[X]$ , we have  $R(W) = W^G$ .
- (e) If  $X$  is an affine  $G$ -variety, the Reynolds operator for  $K[X]$  is unique

*Proof.*

(a)

Let  $V$  be a subrepresentation of a rational representation  $V'$  of  $G$ . We write  $V = V^G \oplus W$  and  $V' = (V')^G \oplus W'$ , where  $W$  and  $W'$  are each the unique subrepresentations of  $V$  and  $V'$  respectively with this property as in our assumption. Let  $w \in W$ . We write  $w = u' + w'$  where  $u' \in (V')^G$  and  $w' \in W'$ . We choose a basis  $\{u'_i\}_{i \in [r]}$  of  $(V')^G$  and  $\{w'_j\}_{j \in [s]}$  of  $W'$  and write  $w = \sum_{i=1}^r \lambda_i u'_i + \sum_{j=1}^s \mu_j w'_j$ . For  $i \in [r]$ , let us consider  $\hat{u}'_i \in (V')^*$ , the dual basis element of  $u'_i$  with respect to the basis  $\{u'_i\}_{i \in [r]} \cup \{w'_j\}_{j \in [s]}$  of  $V'$ . Because of our assumption we have  $(W^*)^G = \{0\}$ , so we must have  $\hat{u}'_i|_W = 0$ , and therefore  $\lambda_i = \hat{u}'_i(w) = \hat{u}'_i|_W(w) = 0$ . We retrieve  $u' = 0$ , implying  $w = w' \in W'$ . We have now shown  $W \subseteq W'$ . Let  $v \in V$ . With  $V^G \subseteq (V')^G$

<sup>1</sup>We here view  $R_V: V \rightarrow V^G$  as  $R_V: V \rightarrow V$ .

and  $R_V(v) - v \in W \subseteq W'$ , we retrieve  $R_{V'}(v) - R_V(v) = R_{V'}(v - R_V(v)) = 0$ . This concludes  $R_{V'}|_V = R_V$ .

(b)

Let  $V$  be a rational representation of  $G$ , and let  $R'_V: V \rightarrow Y$  be a  $G$ -invariant linear map where  $V \subseteq Y$ . Via our assumption, we can find a unique subrepresentation  $W$  of  $V$  such that  $V = V^G \oplus W$ . We obviously have  $R'_V|_{V^G} = \text{id}_{V^G} = R_V|_{V^G}$ . Let  $w \in W$ . We choose a basis  $\{w_i\}_{i \in [r]}$  of  $U := \text{span}(W + R'_V(w))$ , and we write  $R'_V(w) = \sum_{i=1}^r \lambda_i w_i$ . Let  $\{w'_i\}_{i \in [r]}$  be the basis of  $U^*$  dual to the previously mentioned basis of  $U$ . For  $i \in [r]$ , we have  $(w'_i \circ R'_V)|_W \in (W^*)^G = \{0\}$  via our assumption, and therefore  $\lambda_i = w'_i(R'_V(w)) = (w'_i \circ R'_V)|_W(w) = 0$ . This means that  $R(w) = 0$ . We now have shown  $R|_W = 0$ . This concludes that  $R'_V = R_V$ .

(c)

This follows immediately from (b): If  $X$  is an affine  $G$ -variety and  $R: K[X] \rightarrow K[X]^G$  is a Reynolds operator and  $V$  is a  $G$ -stable subspace of  $K[X]$ , we have that  $R|_V: V \rightarrow K[X]$  is a linear map with  $V \subseteq K[X]$  and  $R_V|_{V^G} = \text{id}_{V^G}$ . Therefore we have  $R|_V = R_V$ .

(d)

Let  $X$  be an affine  $G$ -variety,  $R: K[X] \rightarrow K[X]^G$  a Reynolds operator and  $W$  any  $G$ -stable subspace of  $K[X]$ . now let  $w \in W$ . Since  $W$  is  $G$ -stable we have  $V_w \subseteq W$  and with (c) therefore  $R(w) = R_{V_w}(w) \in V_w^G \subseteq W^G$ . We have therefore shown  $R(W) \subseteq W^G$ . Also  $R|_{W^G} = \text{id}_{W^G}$  since  $W^G \subseteq K[X]^G$ , concluding  $R(W) = W^G$ .

(e)

This follows immediately from (c): Let  $X$  be an affine  $G$ -variety and  $R_1, R_2: K[X] \rightarrow K[X]^G$  each a Reynolds operator. Now let  $f \in K[X]$ . Then  $R_1(f) = R_{V_f}(f) = R_2(f)$ .  $\square$

### Remark 3.5.1

$K[V]_d$ , that is the subspace of all homogeneous polynomials of degree  $d$ , is a  $G$ -stable subspace of  $K[V]$ . Since  $K[V] = \bigoplus_{d \geq 0} K[X]_d$ , we therefore also have  $K[V]^G = \bigoplus_{d \geq 0} K[V]_d^G$ , which means that all  $R_{K[X]_d}$  characterize  $R$ . This is important for the proof of Hilbert's finiteness theorem.

### Remark 3.5.2

Note that in lemma 3.5(e) we just showed uniqueness without mentioning existence. In the following, we see that in fact there always exists a Reynolds operator for groups with the previously described properties.

### Theorem 3.6

Let  $G$  be a linear algebraic group. The following are equivalent:

- (a)  $G$  is linearly reductive
- (b) For every rational representation  $V$  of  $G$  there exists a unique subrepresentation  $W$  with  $V = V^G \oplus W$ . For this subrepresentation  $W$  we have  $(W^*)^G = \{0\}$ .

- (c) For every affine  $G$ -variety  $X$  there exists a Reynolds operator  $R: K[X] \rightarrow K[X]^G$ .

*Proof.*

(a)  $\implies$  (b)

Let  $V$  be a rational representation of  $G$ . Consider the subspace  $((V^*)^G)^\perp \subseteq V$ . It is easily seen that this is a subrepresentation of  $V$ . Since by (a)  $(V^*)^G$  and  $V^G$  are dual to each other, we have  $V = V^G \oplus ((V^*)^G)^\perp$ . We have shown the existence, now we shall show uniqueness. Let  $W$  be a subrepresentation of  $V$  with  $V = V^G \oplus W$ . Again, it is easily seen that  $W^\perp \subseteq V^*$  is a subrepresentation.  $G$  must act trivially on  $W^\perp \subseteq V^*$ : Let  $f \in W^\perp$ , and let  $\sigma \in G$ . We have  $\sigma.f \in W^\perp$  and therefore  $\sigma.f - f \in W^\perp$ . Now, let  $v \in V$ . We write  $v = u + w$  for (unique)  $u \in V^G$  and  $w \in W$  and compute:

$$\begin{aligned} (\sigma.f - f)(v) &= (\sigma.f - f)(u) + (\sigma.f - f)(w) \\ &= f(\sigma^{-1}.u) - f(u) + 0 \\ &= f(u) - f(u) = 0 \end{aligned} \tag{6}$$

Which means that  $\sigma.f = f$ . Hence  $G$  does act trivially on  $W^\perp$ . This means that  $W^\perp \subseteq (V^*)^G$ . But we also have  $\dim W^\perp = \dim V^G = \dim (V^*)^G$ , which implies  $W^\perp = (V^*)^G$ , and therefore also  $W = (W^\perp)^\perp = ((V^*)^G)^\perp$ , which concludes the claim of uniqueness. Finally, we notice that  $W$  and  $W^*$  are isomorphic representations (!), which also means that  $(W^*)^G$  and  $W^G$  are isomorphic. Since we have  $W^G = \{0\}$ , we therefore must also have  $(W^*)^G = \{0\}$ .

(b)  $\implies$  (c)

Let  $X$  be an affine  $G$ -variety. Let  $f \in K[X]$ . We define the map  $R: K[X] \rightarrow K[X]^G$ ,  $f \mapsto R_{V_f}(f)$ . For  $f \in K[X]$  we denote by  $W_f$  the unique subrepresentation of  $V_f$  such that  $V_f = V_f^G \oplus W_f$  as in (b). This map is linear: Let  $f, g \in K[X]$  and  $\lambda \in K$ . We notice that  $V_f, V_g, V_{\lambda f + g} \subseteq V_f + V_g$ , which together with lemma 3.5(a) gives us  $R(\lambda f + g) = R_{V_{\lambda f + g}}(\lambda f + g) = R_{V_f + V_g}(\lambda f + g) = \lambda R_{V_f + V_g}(f) + R_{V_f + V_g}(g) = \lambda R_{V_f}(f) + R_{V_g}(g) = \lambda R(f) + R(g)$ . The map  $R$  is also a projection onto  $K[X]^G$ , since for each  $f \in K[X]$  we have  $V_f^G \subseteq K[X]^G$ .  $R$  is also  $G$ -invariant, since for all  $f \in K[X]$   $R_{V_f}$  is  $G$ -invariant and for all  $\sigma \in G$  we have  $V_f = V_{\sigma.f}$ . This concludes that  $R$  is a Reynolds operator, which shows (c).

(c)  $\implies$  (a)

Let  $V$  be a rational representation of  $G$  and let  $v \in V^G \setminus \{0\}$ . We choose a basis  $\{v_i\}_{i \in [r]}$  of  $V$  with  $v_1 = v$ . Let  $\tilde{v} \in V^*$  be the dual basis vector of  $v$  with respect to the afore mentioned basis. Now we define  $p_v: K[V^*] \rightarrow K$ ,  $f \mapsto f(\tilde{v})$ . Consider the isomorphism of representations  $\Phi: V \rightarrow (V^*)^*$ ,  $w \mapsto (\varphi \mapsto \varphi(w))$ . We have  $(V^*)^* \subseteq K[V^*]$ . Since  $V^*$  is a rational representation and since via our assumption (c) there exists a Reynolds operator  $R: K[V^*] \rightarrow K[V^*]^G$ , we can define  $\psi_v := p_v \circ R \circ \Phi: V \rightarrow K$ . Since each map is linear, we have  $\psi_v \in V^*$ , and since the Reynolds operator is used, we can also see that we have  $\psi_v \in (V^*)^G$ . We notice that since  $v \in V^G$  we have  $\Phi(v) \in K[V^*]^G$ , implying  $R(\Phi(v)) = \Phi(v)$  and therefore  $\psi_v(v) = p_v(\Phi(v)) = \Phi(v)(\tilde{v}) = \tilde{v}(v) = 1 \neq 0$ . This implies that

$b|_{(V^*)^G \times V^G}$  is non-degenerate in the left variable.

By what we just showed, if we take any linear invariant  $\varphi \in (V^*)^G \setminus \{0\}$ , we receive an  $A_\varphi \in ((V^*)^G)^G$  such that  $A_\varphi(\varphi) = 1$ . Since  $\Phi$  is an isomorphism of representations, we have  $v_\varphi := \Phi^{-1}(A_\varphi) \in V^G$  and  $\varphi(v_\varphi) = \varphi(\Phi^{-1}(A_\varphi)) = A_\varphi(\varphi) = 1$ . This shows that  $b|_{(V^*)^G \times V^G}$  is also non-degenerate in the second variable.

This concludes that  $G$  is linearly reductive, showing (a).  $\square$

### Theorem 3.7

If  $K$  is an algebraically closed field, then a linear algebraic group  $G$  is linearly reductive if and only if  $G$  is semisimple, that is for every rational representation  $V$  of  $G$  and subrepresentation  $W$  of  $V$  there exists a subrepresentation  $Z$  of  $V$  such that  $V = W \oplus Z$ .

*Proof.* Assume that  $G$  is linearly reductive and let  $V$  be a rational representation of  $G$ .

Let us first assume that we have an irreducible subrepresentation  $W$  of  $V$ . We can identify  $\text{Hom}_K(W, V)^*$  with  $\text{Hom}_K(V, W)$  via the isomorphism  $A \leftrightarrow (B \mapsto k^{-1} \text{tr}(A \circ B))$  where  $k \in \mathbb{N}$  is the dimension of  $W$ . If we let  $G$  act on  $\text{Hom}_K(W, V)$  by  $\sigma.B := w \mapsto \sigma.(B(w))$  and on  $\text{Hom}_K(V, W)$  by  $\sigma.A := v \mapsto A(\sigma^{-1}.v)$ , we then see that our identification  $A \leftrightarrow (B \mapsto k^{-1} \text{tr}(A \circ B))$  is an isomorphism of representations between  $\text{Hom}_K(W, V)^*$  and  $\text{Hom}_K(V, W)$ . Now let  $B \in \text{Hom}_K(W, V)^G$  be the inclusion map. Since  $G$  is linearly reductive, there exists an  $A \in \text{Hom}_K(V, W)^G$  such that  $k^{-1} \text{tr}(A \circ B) \neq 0$ . Since  $K$  is algebraically closed and since  $W$  is irreducible, Schur's lemma (see [FH91, 1.7]) gives us that  $A \circ B$  must be a non-zero multiple of the identity map. Therefore, if  $Z$  is the kernel of  $A$ , which is a subrepresentation of  $V$  since  $A$  is  $G$ -invariant, we have  $V = W \oplus Z$ .

Now let us prove the claim for an arbitrary subrepresentation  $W$  of  $V$  by induction over  $k := \dim W$ . If  $k = 0$  the statement is trivial. Assume that for  $k \in \mathbb{N}$  the statement is true for all  $m \leq k$ . Now let  $\dim W = k + 1$ . We choose a non-trivial irreducible subrepresentation of  $W$ , say  $W' := \text{span } G.w$  for some  $w \in W \setminus \{0\}$ . By what we showed earlier, there exists a subrepresentation  $Z'$  of  $V$  such that  $V = W' \oplus Z'$ . We also have that  $W \cap Z'$  is a subrepresentation of  $V$  and  $W = W' \oplus W \cap Z'$ . Since  $W'$  is non-trivial, we get  $\dim W \cap Z' \leq k$ , and therefore by induction hypothesis there exists a subrepresentation  $Z$  of  $Z'$  such that  $Z' = W \cap Z' \oplus Z$ . We then have  $V = W' \oplus Z' = W' \oplus W \cap Z' \oplus Z = W \oplus Z$ . This shows the forwards implication of our initial claim.

Now assume that for every rational representation  $V$  of  $G$  and subrepresentation  $W$  of  $V$  there exists a subrepresentation  $Z$  of  $V$  such that  $V = W \oplus Z$ . Let  $V$  be a rational representation of  $G$ . By our assumption there exists a subrepresentation  $W$  of  $V$  such that  $V = V^G \oplus W$ . If we have  $v \in V^G \setminus \{0\}$ , we can extend to a basis  $B_{V^G}$  of  $V^G$  with  $v \in B_{V^G}$ . Now we choose any basis  $B_W$  of  $W$  and can define  $\varphi_v \in V^*$  to be the dual vector of  $v$  with respect to the basis  $B_{V^G} \cup B_W$  of  $V$ . We then have  $\varphi_v \in (V^*)^G$  and  $\varphi_v(v) = 1 \neq 0$ . This shows that  $b|_{(V^*)^G \times V^G}$  is non-degenerate in the left variable. We use the same steps to show non-degeneracy

in the right variable: By assumption, we there exists a subrepresentation  $Z$  of  $V^*$  with  $V^* = (V^*)^G \oplus Z$ . If we have  $\varphi \in (V^*)^G \setminus \{0\}$ , we can choose a basis  $B_{(V^*)^G}$  of  $(V^*)^G$  with  $\varphi \in B_{(V^*)^G}$ . Now, for some basis  $B_Z$  of  $Z$  we define  $v_\varphi \in V$  to be the dual vector of  $\varphi$  with respect to the basis  $B_{(V^*)^G} \cup B_Z$  of  $V^*$ . We notice that  $v_\varphi \in V^G$  and  $\varphi(v_\varphi) = 1 \neq 0$ , showing that  $b|_{(V^*)^G \times V^G}$  is non-degenerate in the right variable. This concludes that  $G$  is linearly reductive. We have now proven both implications of our claim.  $\square$

### 3.2 Hilbert's Finiteness Theorem

#### Proposition 3.8

See [DK15, p.41 Corollary 2.2.7]

Let  $G$  be a linearly reductive group, and let  $R: K[X] \rightarrow K[X]^G$  be the Reynolds operator for an affine  $G$ -variety  $X$ . If  $f \in K[X]^G$  and  $g \in K[X]$  we have  $R(fg) = fR(g)$ , id est the Reynolds operator is a  $K[X]^G$ -module homomorphism.

*Proof.* Let  $f \in K[X]^G$  and  $g \in K[X]$ . By theorem 3.6, we can decompose  $V_g = V_g^G \oplus W_g$  uniquely, where  $W_g$  is a subrepresentation of  $V_g$ , and we also have  $(W_g^*)^G = \{0\}$ .  $fV_g$  is also a representation of  $G$  with subrepresentations  $fV_g^G$  and  $fW_g$  of  $G$  and we notice that  $(fV_g)^G = fV_g^G$ . We easily check that the map  $R'_{fV_g}: fV_g \rightarrow fV_g$ ,  $fh \mapsto fR(h)$  is a  $G$ -invariant linear map with  $R'_{fV_g}|_{(fV_g)^G} = \text{id}_{(fV_g)^G}$ , which by lemma 3.5(b) means that we have  $R'_{(fV_g)} = R_{(fV_g)}$ , which means that we have  $R(fg) = fR(g)$ .  $\square$

#### Theorem 3.9: Hilbert's Finiteness Theorem

If  $G$  is linearly reductive and  $V$  is a finite-dimensional rational  $G$ -representation, the invariant ring  $K[V]^G$  is finitely generated.

*Proof.* Let  $I_{>0}$  denote the ideal generated by all non-constant invariants in  $K[V]$ . Since  $K[V]$  is noetherian, there exist finitely many linearly independent invariants  $\{f_i\}_{i \in [r]} \subseteq K[V]^G$  such that  $(\{f_i\}_{i \in [r]}) = I_{>0}$ . We claim  $K[\{f_i\}_{i \in [r]}] = K[V]^G$ . The inclusion " $\subseteq$ " is clear. To show is " $\supseteq$ ". This is equivalent to showing that for all  $d \in \mathbb{N}$  we have  $K[V]_{\leq d}^G \subseteq K[\{f_i\}_{i \in [r]}]$ . We will show our claim via induction over the degree  $d$ . For  $g \in K[V]_{\leq 1}^G = K$  we are already done since  $K \subseteq K[\{f_i\}_{i \in [r]}]$ . Now assume that for  $d \in \mathbb{N}$  we have  $K[V]_{\leq d}^G \subseteq K[\{f_i\}_{i \in [r]}]$ . Let  $g \in K[V]_{\leq d+1}^G$ . By construction,  $g \in I_{>0}$ , therefore there exist  $\{g_i\}_{i \in [r]} \subseteq K[V]$  such that  $g = \sum_{i=1}^r g_i f_i$ . Since the  $f_i$  are non-constant and linearly independent, and since  $\deg g < d+1$ , we must have  $\deg g_i < d$ . We now make use of the Reynolds Operator:

$$g = R(g) = R\left(\sum_{i=1}^r g_i f_i\right) = \sum_{i=1}^r R(g_i) f_i \quad (7)$$

Since  $R$  maps  $K[V]_{\leq d}$  to  $K[V]_{\leq d}^G$ , we have  $R(g_i) \in K[V]_{\leq d}^G \subseteq K[\{f_i\}_{i \in [r]}]$  by our induction hypothesis. This finally implies  $g \in K[\{f_i\}_{i \in [r]}]$ , which concludes

our proof: We have  $K[V]^G = K[\{f_i\}_{i \in [r]}]$  which means that  $K[V]^G$  is finitely generated, which was to show.  $\square$

### Example 3.9.1

Let  $K$  be an algebraically-closed field. Consider  $\mathrm{GL}_n$  viewed as the group of all change-of-coordinates transformations for endomorphisms on  $K^n$ , that is the rational representation

$$\begin{aligned} \mu: \quad \mathrm{GL}_n \times V &\longrightarrow V \\ (\sigma, A) &\longmapsto \sigma A \sigma^{-1} \end{aligned} \tag{8}$$

where  $V = K^{n \times n}$ . We will later show that  $\mathrm{GL}_n$  is linearly reductive. Hilbert's finiteness theorem then gives us that  $K[V]^{\mathrm{GL}_n}$  is finitely generated.

What exactly are the invariants? The invariants are exactly those polynomials that are independent of the choice of the basis. The most well-known invariant is the determinant. From this observation we can find even more: We can follow that the characteristic polynomial of a matrix  $A$ , that is  $\det(tI_n - A)$ , does not change under a change of coordinates. If we write

$$\det(tI_n - A) = \sum_{i=0}^n p_{n,i}(A)t^i \tag{9}$$

this means that every  $p_{n,i}$  is an invariant polynomial in  $K[K^{n \times n}]$ ! This is how one usually proves that the trace is an invariant polynomial after observing that  $p_{n,n-1} = \mathrm{tr}_n$ . Are there other invariants than these  $p_{n,i}$ ? No! To see this, we will use a little trick: Consider  $D := \{ \delta \in V \mid \delta \text{ diagonalizable} \} \subseteq K[V]$ . Since  $M := \{ A \in V \mid \mathrm{disc}(\det(tI_n - A)) \neq 0 \}$  is Zariski-open and therefore Zariski-dense in  $V$ , and since  $M \subseteq D$ , we also have that  $D$  is Zariski-dense in  $V$ . For this reason, we will look at the evaluation of an invariant polynomial  $p \in K[V]$  only on elements in  $D$ , and can deduce what polynomial it is.

Let  $p \in K[V]^{\mathrm{GL}_n}$ . We define a projection onto the diagonal:  $\pi: K^{n \times n} \rightarrow K^n, [A_{i,j}]_{i,j \in [n]} \mapsto (A_{i,i})_{i \in [n]}$ . Consider  $\tilde{p} := p \circ \mathrm{diag}$ . We claim that  $\tilde{p}$  is  $S_n$ -invariant: If  $M_\tau \in \mathrm{GL}_n$  is the permutation matrix corresponding to  $\tau \in S_n$ , then for all  $\tau \in S_n$  and for all  $X \in K^n$  we have

$$\begin{aligned} \tau.\tilde{p}(X) &= \tilde{p}(\tau^{-1}.X) \\ &= p(\mathrm{diag}(\tau^{-1}.X)) \\ &= p(M_\tau^{-1} \cdot \mathrm{diag}(X)) \\ &= M_\tau.p(\mathrm{diag}(X)) \\ &= p(\mathrm{diag}(X)) = \tilde{p}(X) \end{aligned} \tag{10}$$

From the fundamental theorem of symmetric polynomials we can follow that  $\tilde{p} \in \mathrm{span}\{e_{n,i}\}_{i=0}^n$ , say  $\tilde{p} = \sum_{i=0}^n \lambda_i e_{n,i}$ , where  $\{e_{n,i}\}_{i=0}^n$  are the elementary symmetric polynomials of dimension  $n$ . Now, for a choice of  $\sigma_A \in \mathrm{GL}_n$  such that  $\sigma_A.A$  is diagonal, we easily see that for  $s(A) := \sigma_A.A$  we get  $p = p \circ s = \tilde{p} \circ \pi \circ s$ ,

therefore  $p = \sum_{i=0}^n \lambda_i e_{n,i} \circ \pi \circ s$ . Now we want to show that  $e_{n,i} \circ \pi \circ s = p_{n,i}$ , which would conclude our claim. For all  $A \in D$  we have

$$\begin{aligned} \sum_{i=0}^n (e_{n,i} \circ \pi \circ s)(A) t^i &= \det(t - \sigma_A \cdot A) \\ &= \det(t - A) = \sum_{i=0}^n p_{n,i}(A) t^i \end{aligned} \tag{11}$$

which shows our claim. Note that this is independent of the choice of  $s$ , which means that we don't need the axiom of choice.

We now showed that the invariant ring  $K[V]^{\mathrm{GL}_n}$  is finiteley generated independently of Hilbert's finiteness theorem. We will later show that  $\mathrm{GL}_n$  is linearly reductive. Hilbert's finiteness theorem then gives us the immediate answer, though without giving us the generators of the invariant ring.

### Example 3.9.2

Assume that  $K$  is algebraically closed. Consider the group  $G = \mathrm{SL}_n$  and the vector space  $V = \{ A \in K^{n \times n} \mid A^T = A \}$ . Now we will look at the following action:

$$\begin{aligned} \mu: \quad \mathrm{SL}_n \times V &\longrightarrow V \\ (S, A) &\longmapsto SAS^T \end{aligned} \tag{12}$$

which defines a rational representation of  $\mathrm{SL}_n$ . We claim that  $K[V]^{\mathrm{SL}_n} = K[\det(Z)]^1$ .

For  $B \in K^{n,n}$ , we define  $A' := \mathrm{diag}(b_i)_{i \in [n]}$  where  $b_1 := \det(B)$  and  $a_i := 1$  for  $2 \leq i \leq n$  as in corollary 4.4.1. Now assume that  $f \in K[V]^{\mathrm{SL}_n}$ . Define  $h := (B \mapsto f(B')) \in K[\det(Z)]$ . We claim that  $f = h$ . Since  $X := \{ A \in V \mid \det(A) \neq 0 \}$  is zariski-dense in  $V$ , we have  $g_1(A) = g_2(A)$  for all  $A \in X$  if and only if  $g_1 = g_2$  for  $g_1, g_2 \in K[V]$ . Now let  $A \in X$ . There exists a  $\sigma \in \mathrm{SL}_n$  such that  $\sigma \cdot A = \sigma A \sigma^T$  is a diagonal matrix, say  $\sigma \cdot A = \mathrm{diag}(\lambda_i)_{i \in [n]}$  (!!). We have  $\det(A) = \prod_{i=1}^n \lambda_i$ . Since  $A \in X$ , we have  $\lambda_i \neq 0$  for all  $i \in [n]$ . Using that  $K$  is algebraically closed, we define  $\nu_1 := (\prod_{i=2}^n \lambda_i)^{1/2}$  and  $\nu_i := \lambda_i^{-1/2}$  for  $2 \leq i \leq n$  and receive  $\tau := \mathrm{diag}(\nu_i)_{i \in [n]} \in \mathrm{SL}_n$ . This leads to us having  $\tau \cdot \mathrm{diag}(\lambda_i)_{i \in [n]} = A'$ , implying  $f(A) = (\tau \sigma)^{-1} \cdot f(A) = f(A') = h(A)$ , which shows  $f = h \in K[\det(Z)]$ . Conversely, it should be clear that we have  $K[\det(Z)] \subseteq K[V]^{\mathrm{SL}_n}$ , which concludes  $K[\det(Z)] = K[V]^{\mathrm{SL}_n}$ .

As in the previous example, we have shown that the invariant ring  $K[V]^{\mathrm{SL}_n}$  is finitely generated without Hilbert's finiteness theorem, which after we show that  $\mathrm{SL}_n$  is linearly reductive, gives us the answer that the invariant ring is finitely generated more quickly.

### Lemma 3.10

See [DK15, 2.2.8]

---

<sup>1</sup>  $Z = [Z_{\min\{i,j\}, \max\{i,j\}}]_{i,j \in [n]}$  is to be viewed as the symmetric matrix of the coordinate functions.

Let  $K$  be an algebraically closed field and  $V$  and  $W$  be rational representations of a linearly reductive group  $G$ . For a surjective  $G$ -equivariant linear map  $A: V \twoheadrightarrow W$  we then have  $A(V^G) = W^G$ .

*Proof.* Let  $A: V \twoheadrightarrow W$  be a surjective  $G$ -equivariant linear map. Let  $Z := \ker A$ , which is a subrepresentation of  $V$  since  $A$  is  $G$ -equivariant. Since  $G$  is linearly reductive and since  $K$  is algebraically closed, we can apply theorem 3.7 and get a subrepresentation  $W'$  of  $V$  such that  $V = Z \oplus W'$ . This yields an isomorphism of representations  $A|_{W'}: W' \xrightarrow{\sim} W$ , which implies  $A(V^G) = A(Z^G + W'^G) = A(W'^G) = A(W')^G = W^G$ .  $\square$

**Lemma 3.11**

See [DK15, A1.9].

Let  $X$  be an affine  $G$ -variety. Then there exists a rational representation  $V$  of  $G$  and a  $G$ -equivariant embedding  $i: X \hookrightarrow V$ .

*Proof.* We choose generators  $\{f_i\}_{i \in [r]}$  of  $K[X]$  and define  $W := \sum_{i \in [r]} V_{f_i}$ , which is a finite-dimensional  $G$ -stable subspace of  $K[X]$  containing  $\{f_i\}_{i \in [r]}$ . This gives us the  $G$ -invariant morphism of affine varieties  $i: X \rightarrow W^*$ ,  $x \mapsto (w \mapsto w(x))$ . This is injective, since  $W$  contains a generating set of  $K[X]$ , which means that  $i$  is an embedding.  $\square$

**Example 3.11.1: The Domain Of The Cross Ratio**

We would like to look at four distinct points in the projective line over an algebraically closed field  $K$ . Since the projective line isn't an affine variety, we will look at points in  $K^2$  to make the situation affine, which will make some things different from the setting in projective geometry.

Consider  $(K^2)^4$  and the coordinate functions  $\{(X_i)_k\}_{i \in [4], k \in [2]}$ . We write  $X_i = \begin{pmatrix} (X_i)_1 \\ (X_i)_2 \end{pmatrix}$  for  $i \in [4]$ . Define  $q := \prod_{i,j \in [r], i < j} \det(X_i, X_j)$ . As described in 2.1, we have an affine variety

$$X := \{ (x_1, x_2, x_3, x_4) \in (K^2)^4 \mid q(x_1, x_2, x_3, x_4) \neq 0 \} \quad (13)$$

with the coordinate ring  $K[X] = K[\{(X_i)_k\}_{i \in [4], k \in [2]}, q^{-1}]$ . Now consider the rational linear action of  $\mathrm{GL}_2$  on  $X$  via pointwise application, that is  $\mu: \mathrm{GL}_2 \times X \rightarrow X$ ,  $(\sigma, (x_1, x_2, x_3, x_4)) \mapsto (\sigma x_1, \sigma x_2, \sigma x_3, \sigma x_4)$ . The Rabinowitsch-trick gives us the inclusion  $i: X \hookrightarrow K \times (K^2)^4$  as described in proposition 2.1. If we define an action on  $K \times (K^2)^4$  by  $(\sigma, (z, x_1, x_2, x_3, x_4)) \mapsto (\det(\sigma)^{-6} z, \sigma x_1, \sigma x_2, \sigma x_3, \sigma x_4)$ , it should be clear that  $i$  is a  $\mathrm{GL}_2$ -equivariant morphism of affine varieties.

**Lemma 3.12**

See [DK15, 2.2.9].

Assume that  $K$  is algebraically closed and that  $G$  is linearly reductive. Let  $X$  be an affine  $G$ -variety,  $V$  a rational representation of  $G$  and  $i: X \hookrightarrow V$  a  $G$ -equivariant embedding. The surjective  $G$ -equivariant ring homomorphism  $i^*: K[V] \twoheadrightarrow K[X]$  then has the property  $i^*(K[V]^G) = K[X]^G$ .

*Proof.* We obviously have  $i^*(K[X]^G) \subseteq K[X]^G$ . Now let  $f \in K[X]^G$ . We have that  $V_f = \text{span}(f)$  is a  $G$ -stable subspace of  $K[X]$ , and since  $i^*$  is surjective, there exists a  $g \in K[V]$  such that  $i^*(g) = f$ . Since  $i^*$  is  $G$ -equivariant,  $\text{span } g$  is a  $G$ -stable subspace of  $K[V]$  with  $i^*(\text{span } g) = \text{span}(f)$ . By lemma 3.10 we have  $i^*((\text{span } g)^G) = (\text{span } f)^G$ , in particular  $f \in i^*((\text{span } g)^G) \subseteq i^*(K[V]^G)$ . This concludes  $i^*(K[V]^G) = K[X]^G$ .  $\square$

**Theorem 3.13: Hilbert's Finiteness Theorem For Affine Varieties**

If  $K$  is an algebraically closed field,  $G$  a linearly reductive group and  $X$  is an affine  $G$ -variety,  $K[X]^G$  is finitely generated.

*Proof.* By lemma 3.11, there exists a rational representation  $V$  of  $G$  and an embedding  $i: X \hookrightarrow V$ . By theorem 3.9 there exist  $\{f_i\}_{i \in [r]} \subseteq K[V]$  such that  $K[V]^G = K[\{f_i\}_{i \in [r]}]$ . By lemma 3.12 we have  $K[X]^G = i^*(K[V]^G) = i^*(K[\{f_i\}_{i \in [r]}]) = K[\{i^*(f_i)\}_{i \in [r]}]$ , which shows that  $K[X]^G$  is finitely generated.  $\square$

**Example 3.13.1: The Domain of the Cross Ratio**

Consider example 3.11.1, that is the affine  $\text{GL}_2$ -variety  $X := \{(x_1, x_2, x_3, x_4) \in (K^2)^4 \mid q(x_1, x_2, x_3, x_4) \neq 0\}$ , where  $q := \prod_{i,j \in [r], i < j} \det(X_i, X_j)$ , with the coordinate ring  $K[X] = K[\{(X_i)_k\}_{i \in [4], k \in [2]}, q^{-1}]$  and the linear rational action by pointwise application, that is  $\mu: \text{GL}_2 \times X \rightarrow X$ ,  $(\sigma, (x_1, x_2, x_3, x_4)) \mapsto (\sigma x_1, \sigma x_2, \sigma x_3, \sigma x_4)$ . Our condition  $q(x_1, x_2, x_3, x_4) \neq 0$  is equivalent to saying that for  $i \neq j$  we have  $x_i \notin \text{span } x_j$ , which allows us to define the cross ratio  $\text{cr} \in K[X]$  as follows

$$\begin{aligned} \text{cr}: \quad X &\rightarrow K \\ (x_1, x_2, x_3, x_4) &\mapsto \frac{\det(x_1, x_2) \det(x_3, x_4)}{\det(x_2, x_3) \det(x_4, x_1)} \end{aligned} \quad (14)$$

This map, along with the maps  $\{\text{cr}(X_{\pi_1}, X_{\pi_2}, X_{\pi_3}, X_{\pi_4})\}_{\pi \in S_4}$ , is an invariant. This is very important in projective geometry.

We now ask question of how many other invariants exist. In this affine setting, Hilbert's finiteness theorem gives us that the ring of all invariants  $K[X]$  is finitely generated, but it does not give us an idea of what they look like, or if invariants other than the ones mentioned exist.

### 3.3 The Reynolds Operator Of A Group

In theorem 3.6 we have learned about three characterizations of linearly reductive groups, but for a given linear algebraic group, it is still hard to concretely show that it is linearly reductive. We will soon learn about an additional way to characterize linearly reductive groups, which will motivate Cayley's  $\Omega$ -process.

**Definition 3.14: Reynolds Operator Of A Group**

Let  $G$  be a linear algebraic group. The multiplication  $m: G \times G \rightarrow G$  makes  $G$  a  $G$ -variety. Assume that for this action there exists a Reynolds operator

$R_G: K[G] \rightarrow K[G]^G = K$  which is  $G$ -invariant from the left and from the right, that is for all  $\sigma \in G$  and  $p \in K[G]$  we not only have  $R_G(\sigma.p) = R_G(p)$ , but also  $R_G(\sigma.p) = R_G(p)$  (see definition 2.10). We call  $R_G$  the *Reynolds operator* of  $G$ .

**Definition 3.15**

Define the multiplication on  $K[G]^*$ , denoted by  $*$ , as follows: For  $\alpha, \beta \in K[G]^*$ :

$$\alpha * \beta := (\alpha \otimes \beta) \circ m^* \quad (15)$$

More slowly: If for  $f \in K[G]$  we have  $m^*(f) = \sum_i g_i \otimes h_i \in K[G] \otimes K[X]$ , we then get  $(\alpha * \beta)(f) = \sum_i \alpha(g_i) \beta(h_i)$ .

**Proposition 3.16**

The multiplication  $*$  makes  $K[G]^*$  into an associative algebra with the neutral element  $\epsilon := \epsilon_e$  (Note:  $\epsilon_\sigma(f) = f(\sigma)$ ).

(See [DK15, A2.2])

*Proof.* From the associativity of the multiplication of the group  $G$ , that is for all  $\alpha, \beta, \mu \in G$  we have  $m(m(\alpha, \beta), \mu) = m(\alpha, m(\beta, \mu))$ , we observe that

$$(m^* \otimes \text{id}) \circ m^* = (\text{id} \otimes m^*) \circ m^* \quad (16)$$

holds true.e. Then, for  $\delta, \gamma, \varphi \in K[G]^*$ :

$$\begin{aligned} (\delta * \gamma) * \varphi &= (((\delta \otimes \gamma) \circ m^*) \otimes \varphi) \circ m^* \\ &= ((\delta \otimes \gamma) \otimes \varphi) \circ (m^* \otimes \text{id}) \circ m^* \\ &= (\delta \otimes (\gamma \otimes \varphi)) \circ (\text{id} \otimes m^*) \circ m^* \\ &= (\delta \otimes ((\gamma \otimes \varphi) \circ m^*)) \circ m^* = \delta * (\gamma * \varphi) \end{aligned} \quad (17)$$

showing the associativity. It should be clear that  $\epsilon$  is the neutral element. This concludes that  $K[G]^*$  is an associative algebra.  $\square$

Now we can formally define  $K[G]^*$ -actions.

**Definition 3.17**

Let  $\mu: G \times V \rightarrow V$  be a rational linear action, from which we retrieve  $\mu'$  as described in definition 2.6. For  $\delta \in K[G]^*$  and for  $v \in V$  we define:

$$\delta \cdot v := ((\delta \otimes \text{id}) \circ \mu')(v) \quad (18)$$

**Proposition 3.18**

Definition 3.17 defines a  $K[G]^*$ -algebra-module.

See [DK15, A2.10]

*Proof.* First, we show that this definition defines a group action. We define  $m: G \times G \rightarrow G$  by  $(\sigma, \tau) \mapsto m(\tau, \sigma)$ . We can then observe that

$$(\text{id} \otimes \mu') \circ \mu' = (m^* \otimes \text{id}) \circ \mu' \quad (19)$$

using the fact that  $\mu$  is an action. For any  $\gamma, \delta \in G$  and  $v \in V$  we therefore get

$$\begin{aligned}
\gamma \cdot (\delta \cdot v) &= ((\gamma \otimes \text{id}) \circ \mu' \circ (\delta \otimes \text{id}) \circ \mu')(v) \\
&= ((\gamma \otimes \text{id}) \circ (\delta \otimes \text{id} \otimes \text{id}) \circ (\text{id} \otimes \mu') \circ \mu')(v) \\
&= ((\delta \otimes \gamma \otimes \text{id}) \circ (m^* \otimes \text{id}) \circ \mu')(v) \\
&= (((\gamma \otimes \delta) \circ m^*) \otimes \text{id}) \circ \mu')(v) = (\gamma * \delta) \cdot v
\end{aligned} \tag{20}$$

This concludes that our definition yields an action. Since all operations are linear, we also get that  $V$  is a  $K[G]^*$ -algebra-module.  $\square$

**Remark 3.18.1**

If we look at definition 2.6, we can see that this newly defined  $K[G]^*$ -action is an extension of the given  $G$ -action in the following way: The subgroup  $\{\epsilon_\sigma \mid \sigma \in G\}$  of  $K[G]^*$  is isomorphic to  $G$ , and its induced action coincides with the given action: For  $\sigma \in G$  and for  $v \in V$  we have:

$$\sigma.v = \epsilon_\sigma \cdot v \tag{21}$$

**Theorem 3.19**

Let  $G$  be linearly reductive, and let  $G$  act regularly on an affine variety  $X$ , which induces a rational  $G$ -action on  $K[X]$  as described in definition 2.7. Then, the following the map

$$\begin{aligned}
R: \quad K[X] &\longrightarrow K[X]^G \\
f &\longmapsto R_G \cdot f
\end{aligned} \tag{22}$$

defines a Reynolds operator.

*Proof.* As per our construction from definition 3.17, the linearity of this map should be clear. Let  $f \in K[X]$ ,  $\sigma \in G$  and  $x \in X$ . Write  $\bar{\mu}'(f) = \sum_i p_i \otimes g_i \in K[G] \otimes K[X]$ . Now we compute:

$$\begin{aligned}
\sigma.(R_G \cdot f)(x) &= (R_G \cdot f)(\sigma^{-1}.x) \\
&= \sum_i R_G(p_i) \sigma.g_i(x) \\
&= \sum_i R_G(\sigma.p_i) \sigma.g_i(x) \\
&= (R_G \otimes \text{id})(\sum_i \sigma.p_i \otimes \sigma.g_i)(x) \\
&= (R_G \otimes \text{id})(\bar{\mu}'(f))(x) = (R_G \cdot f)(x)
\end{aligned} \tag{23}$$

We made use of the  $G$ -invariance of  $R_G$  and proposition 2.8. This means that we have  $R(K[X]) \subseteq K[X]^G$ . If  $f \in K[X]^G$ , we have  $\bar{\mu}'(f) = 1 \otimes f$ , therefore  $R(f) = R_G \cdot f = R_G(1)f = f$ . This gives us  $R|_{K[X]^G} = \text{id}_{K[X]^G}$ , showing that  $R$  is a projection of  $K[X]$  onto  $K[X]^G$ .

Now let  $\sigma \in G$  and  $f \in K[X]$ . Assume that we have  $\bar{\mu}'(f) = \sum_{i=1}^r p_i \otimes g_i \subseteq$

$K[G] \otimes K[X]$ . Making use of proposition 2.11, we then get

$$\begin{aligned}
R_G \cdot \sigma.f &= (R_G \otimes \text{id}) (\bar{\mu}'(\sigma.f)) \\
&= (R_G \otimes \text{id}) \left( \sum_{i=1}^r \sigma.p_i \otimes g_i \right) \\
&= \sum_{i=1}^r R_G(\sigma.p_i) g_i \\
&= \sum_{i=1}^r R_G(p_i) g_i = R_G \cdot f
\end{aligned} \tag{24}$$

This shows that  $R$  is  $G$ -invariant, which concludes that  $R$  is the Reynolds operator.  $\square$

### Corollary 3.19.1

If the Reynolds operator of  $G$  exists as described in definition 3.14,  $G$  is linearly reductive. The Reynolds operator of  $G$  is unique.

## 4 Cayley's $\Omega$ -Process

We want to express the Reynolds Operator in a concrete way. For the Group  $\text{GL}_n$ , we can explicitly formulate it with the help of Cayley's  $\Omega$ -Process.

### Definition 4.1: Cayley's $\Omega$ -Process

We call

$$\Omega := \sum_{\sigma \in S_n} \text{sgn}(\sigma) \prod_{i \in [n]} \frac{\partial}{\partial z_{i, \sigma(i)}} \tag{25}$$

**Cayley's  $\Omega$ -Process.** It can also be thought of as  $\Omega = \det \left( \frac{\partial}{\partial Z} \right)$ , where  $\frac{\partial}{\partial Z} := \left[ \frac{\partial}{\partial z_{i,j}} \right]_{i,j \in [n]}$ .

### Lemma 4.2

$$\left( \det(Z)^{-1} \cdot \otimes \Omega \right) \circ m^* = m^* \circ \Omega = \left( \Omega \otimes \det(Z)^{-1} \cdot \right) \circ m^* \tag{26}$$

where we write “ $p \cdot$ ” for the operation *multiply with  $p$*  for a polynomial  $p \in K[\text{GL}_n]$ , that is for  $p, f \in K[\text{GL}_n]$  we have  $p \cdot (f) = pf$ .

*Proof.* Let  $f \in K[\text{GL}_n]$ . We view  $m^*(f) \in K \left[ \{X_{i,j}\}_{i,j \in [n]}, \det(X)^{-1}, \{Y_{i,j}\}_{i,j \in [n]}, \det(Y)^{-1} \right]$  where the  $X_{i,j}$  are associated with the “left” input of  $m$  and the  $Y_{i,j}$  are asso-

ciated with the “right” input of  $m$ . For fixed  $i, j \in [n]$  we have

$$\begin{aligned}
\left( \text{id} \otimes \frac{\partial}{\partial Z_{i,j}} \right) (m^*(f)) &= \frac{\partial}{\partial Y_{i,j}} (f \circ m) \\
&= \sum_{k,l \in [n]} \left( \left( \frac{\partial}{\partial Z_{k,l}} f \right) \circ m \right) \cdot \frac{\partial}{\partial Y_{i,j}} m_{k,l} \\
&= \sum_{k=1}^n \left( \left( \frac{\partial}{\partial Z_{k,j}} f \right) \circ m \right) \cdot X_{k,i} \\
&= \sum_{k=1}^n (Z_{k,i} \cdot \otimes \text{id}) \left( m^* \left( \frac{\partial}{\partial Z_{k,j}} f \right) \right)
\end{aligned} \tag{27}$$

Successively applying this yields

$$\begin{aligned}
(\text{id} \otimes \Omega) (m^*(f)) &= \sum_{\sigma \in S_n} \text{sgn}(\sigma) \left( \text{id} \otimes \prod_{i=1}^n \frac{\partial}{\partial Z_{i,\sigma(i)}} \right) (m^*(f)) \\
&= \sum_{\sigma \in S_n} \text{sgn}(\sigma) \sum_{k \in [n]^n} \left( \prod_{i=1}^n Z_{k(i),i} \cdot \otimes \text{id} \right) \left( m^* \left( \prod_{j=1}^n \frac{\partial}{\partial Z_{k(j),\sigma(j)}} f \right) \right) \\
&= \sum_{k \in [n]^n} \left( \prod_{i=1}^n Z_{k(i),i} \cdot \otimes \text{id} \right) \left( m^* \left( \sum_{\sigma \in S_n} \text{sgn}(\sigma) \prod_{j=1}^n \frac{\partial}{\partial Z_{k(j),\sigma(j)}} f \right) \right) \\
&= \sum_{k \in S_n} \left( \prod_{i=1}^n Z_{k(i),i} \cdot \otimes \text{id} \right) \left( m^* \left( \sum_{\sigma \in S_n} \text{sgn}(\sigma) \prod_{j=1}^n \frac{\partial}{\partial Z_{k(j),\sigma(j)}} f \right) \right) \\
&= \sum_{k \in S_n} \left( \prod_{i=1}^n Z_{k(i),i} \cdot \otimes \text{id} \right) (m^*(\text{sgn}(k)\Omega(f))) \\
&= (\det(Z) \cdot \otimes \text{id}) (m^*(\Omega(f)))
\end{aligned} \tag{28}$$

This immediately shows the first equality, and the second equality is proven analogously.  $\square$

**Lemma 4.3**

For  $p \in \mathbb{N}$ ,  $c_{p,n} := \Omega^p(\det(Z)^p) = \det\left(\frac{\partial}{\partial Z}\right)^p(\det(Z)^p)$  is a nonnegative integer.

*Proof.* Write  $\det(Z)^p = \sum_i a_i q_i \left( \{Z_{k,l}\}_{k,l \in [n]} \right)$ , where  $a_i \in \mathbb{Z} \setminus \{0\}$  and  $q_i$  are (monic) monomials. Then

$$\Omega^p(\det(Z)^p) = \sum_i a_i q_i \left( \left\{ \frac{\partial}{\partial Z_{k,l}} \right\}_{k,l \in [n]} \right) \left( \sum_j a_j q_j \left( \{Z_{k,l}\}_{k,l \in [n]} \right) \right) \tag{29}$$

Notice that  $q_i \left( \left\{ \frac{\partial}{\partial Z_{k,l}} \right\}_{k,l \in [n]} \right) \left( q_j \left( \{Z_{k,l}\}_{k,l \in [n]} \right) \right)$  is zero for  $i \neq j$  and a strictly positive integer for  $i = j$ . Therefore in particular

$$c_{p,n} = \sum_i a_i^2 q_i \left( \left\{ \frac{\partial}{\partial Z_{k,l}} \right\}_{k,l \in [n]} \right) \left( q_i \left( \{Z_{k,l}\}_{k,l \in [n]} \right) \right) \in \mathbb{N}_{>0} \quad (30)$$

□

Now, finally, we have the tools to see the following way of expressing the Reynolds Operator.

**Theorem 4.4**

For  $p \in \mathbb{N}$  and  $\tilde{f} \in K \left[ \{Z_{i,j}\}_{k,l \in [n]} \right]_{pn}$ , define for  $f = \frac{\tilde{f}}{\det(Z)^p}$ :

$$R(f) := \frac{\Omega^p \tilde{f}}{c_{p,n}} \quad (31)$$

The linear extension of this (mapping anything else in  $K[\text{GL}_n]$  to zero), defines the Reynolds Operator  $R_{\text{GL}_n}$ , which makes  $\text{GL}_n$  *linearly reductive*.

*Proof.* First, check that this is well defined: For any such term, expanding the fraction by  $\det(Z)^q$  will yield the same result. Also,  $\Omega^p$  is linear for any  $p \in \mathbb{N}$ . We shall now show that  $R$  is  $\text{GL}_n$ -invariant from the left and from the right.

Let  $p \in \mathbb{N}$ ,  $\tilde{f} \in K[\text{GL}_n]_{pn}$  and  $f := \frac{\tilde{f}}{\det(Z)^p}$ . For  $\beta, \gamma \in \text{GL}_n$ , we notice

$$\begin{aligned} R(\beta.f)(\gamma) &= R \left( \frac{\det(\beta)^p \cdot \beta.\tilde{f}}{\det(Z)^p} \right) (\gamma) \\ &= \frac{\det(\beta)^p \cdot \Omega^p(\beta.\tilde{f})(\gamma)}{c_{p,n}} \\ &= \frac{1}{c_{p,n}} \cdot (\epsilon_{\beta^{-1}} \otimes \epsilon_\gamma) \left( ((\det(Z)^{-p} \cdot \otimes \Omega^p) \circ m^*) (\tilde{f}) \right) \\ &= \frac{1}{c_{p,n}} \cdot (\epsilon_{\beta^{-1}} \otimes \epsilon_\gamma) \left( ((\Omega^p \otimes \det(Z)^{-p}) \circ m^*) (\tilde{f}) \right) \quad (32) \\ &= \frac{\Omega^p(\gamma.\tilde{f})(\beta^{-1}) \cdot \det(\gamma^{-1})^p}{c_{p,n}} \\ &= R \left( \frac{\gamma.\tilde{f} \cdot \det(\gamma^{-1})^p}{\det(Z)^p} \right) (\beta^{-1}) \\ &= R(\gamma.f)(\beta^{-1}) \end{aligned}$$

Since each  $\frac{\partial}{\partial Z_{i,j}}$  lowers the degree of a monomial by one or maps it to zero,  $R$  maps to  $K$ , and therefore for  $\delta \in \text{GL}_n$  and  $g \in K[\text{GL}_n]$  we have  $R(g)(\delta) = R(g) \in K$ . We then get for all  $\beta, \gamma \in \text{GL}_n$

$$R(\beta.f) = R(\beta.f)(\gamma) = R(\gamma.f)(\beta^{-1}) = R(\gamma.f) \quad (33)$$

This implies that for all  $\sigma \in G$  and all  $p \in K[\mathrm{GL}_n]$ , we have  $R(\sigma.p) = R(I_n.p) = R(p)$  and  $R(\sigma.p) = R(I_n.p) = R(p)$ , showing that  $R$  is  $\mathrm{GL}_n$ -invariant from the left and from the right. Finally, the definition immediately gives us that  $R$  restricted to  $K$  is the identity.

This shows that  $R$  is a Reynolds-operator, and as mentioned in lemma 3.5(e), the uniqueness of the Reynolds Operator implies that we can write  $R = R_{\mathrm{GL}_n}$ .  $\square$

Now we will look at the Reynolds Operator  $R_{\mathrm{SL}_n}$ .

**Corollary 4.4.1**

With the identification  $K[\mathrm{GL}_n] = K[\{Z_{k,l}\}_{k,l \in [n]}, \det(Z)^{-1}]$ , view  $K[\mathrm{SL}_n] = K[\mathrm{GL}_n]/I$  where  $I = (\det(Z) - 1)$ . Now, for  $p \in \mathbb{N}$  and  $f \in K[\{Z_{i,j}\}_{k,l \in [n]}]_{pn}$  we define:

$$R(f + I) := R_{\mathrm{GL}_n} \left( \frac{f}{\det(Z)^p} \right) + I = \frac{\Omega^p \tilde{f}}{c_{p,n}} + I \quad (34)$$

The linear extension of this (mapping anything else in  $K[\mathrm{SL}_n]$  to zero), defines the Reynolds Operator  $R_{\mathrm{SL}_n}$ , making  $\mathrm{SL}_n$  *linearly reductive*.

*Proof.* First, we will show  $K[\mathrm{GL}_n]^{\mathrm{SL}_n} = K[\det(Z), \det(Z)^{-1}]$  (action by left multiplication). For  $B \in K^{n,n}$ , define  $B' := \mathrm{diag}(b_i)_{i \in [n]}$ , where  $b_1 := \det(B)$  and  $b_i := 1$  for  $2 \leq i \leq n$ . Let  $g \in K[\mathrm{GL}_n]^{\mathrm{SL}_n}$ , and let  $\alpha \in \mathrm{GL}_n$ . Note that  $\alpha(\alpha')^{-1} \in \mathrm{SL}_n$ . Define  $h := (\beta \mapsto g(\beta')) \in K[\det(Z), \det(Z)^{-1}]$ . We claim that  $g = h$ . This is seen as follows:

$$\begin{aligned} g(\alpha) &= \alpha(\alpha')^{-1}.g(\alpha) = g(\alpha'\alpha^{-1}\alpha) \\ &= g(\alpha') = h(\alpha) \end{aligned} \quad (35)$$

This shows that  $g = h \in K[\det(Z), \det(Z)^{-1}]$ . Conversely it is easy to see that  $K[\det(Z), \det(Z)^{-1}] \subseteq K[\mathrm{GL}_n]^{\mathrm{SL}_n}$ .

Now we define a map  $\hat{R}: K[\mathrm{GL}_n] \rightarrow K[\mathrm{GL}_n]^{\mathrm{SL}_n}$  as follows:

For  $p, r \in \mathbb{N}$ ,  $\tilde{f} \in K[\{Z_{k,l \in [n]}\}]_{rn}$ , and  $f = \frac{\tilde{f}}{\det(Z)^p}$ , define

$$\hat{R}(f) := \det(Z)^{r-p} \cdot \frac{\Omega^r \tilde{f}}{c_{r,n}} = \det(Z)^{r-p} \cdot R_{\mathrm{GL}_n} \left( \frac{\tilde{f}}{\det(Z)^r} \right) \quad (36)$$

As before we define the images of the other elements by linear extension. Well-definedness follows from the same observations as in the proof of the theorem. This map is the identity on  $K[\mathrm{GL}_n]^{\mathrm{SL}_n}$ : If  $f \in K[\mathrm{GL}_n]^{\mathrm{SL}_n}$ , then  $f$  must be a linear combination of terms of the form  $\frac{\det(Z)^r}{\det(Z)^p}$ . Without loss of generality we can assume that either  $p = 0$  or  $r = 0$ . Then it should be clear that  $f$  gets mapped to itself. Finally, we can see that  $\hat{R}$  is  $\mathrm{SL}_n$ -invariant from the left and

from the right: Let  $\alpha \in \text{SL}_n$ . Then

$$\begin{aligned}
\hat{R}(\alpha.f) &= \hat{R} \left( \frac{\det(\alpha)^p \cdot \alpha.\tilde{f}}{\det(Z)^p} \right) \\
&= \det(Z)^{r-p} \cdot R_{\text{GL}_n} \left( \frac{\det(\alpha)^p \cdot \alpha.\tilde{f}}{\det(Z)^r} \right) \\
&= \det(Z)^{r-p} \cdot R_{\text{GL}_n} \left( \frac{\det(\alpha)^r \cdot \alpha.\tilde{f}}{\det(Z)^r} \right) \\
&= \det(Z)^{r-p} \cdot R_{\text{GL}_n} \left( \alpha. \left( \frac{\tilde{f}}{\det(Z)^r} \right) \right) \\
&= \det(Z)^{r-p} \cdot R_{\text{GL}_n} \left( \frac{\tilde{f}}{\det(Z)^r} \right) = \hat{R}(f)
\end{aligned} \tag{37}$$

We used  $\det(\alpha)^p = 1 = \det(\alpha)^r$  and the  $\text{GL}_n$ -invariance of  $R_{\text{GL}_n}$ . The  $\text{GL}_n$ -invariance from the right is shown analogously. Thus we have shown that  $\hat{R}$  is the Reynolds-Operator for the action of  $\text{SL}_n$  on  $\text{GL}_n$  by left-multiplication, which is also  $\text{SL}_n$ -invariant from the right.

Noting that  $\det(Z) \sim 1$ , this shows our proposed statement that  $R = R_{\text{SL}_n}$  does define the Reynolds operator of  $\text{SL}_n$ .  $\square$

#### Example 4.5

We will apply Cayley's  $\Omega$ -process in the setting of example 3.9.2 for  $n = 2$ , that is the group  $G = \text{SL}_2$  and the representation  $V = \{ A \in K^{2 \times 2} \mid A^T = A \}$  with the action

$$\begin{aligned}
\mu: \quad \text{SL}_2 \times V &\longrightarrow V \\
(S, A) &\longmapsto SAS^T
\end{aligned} \tag{38}$$

Now consider the following for  $S \in \text{SL}_2$  and  $A \in V$ :

$$\begin{aligned}
S &= \begin{bmatrix} s_{1,1} & s_{1,2} \\ s_{2,1} & s_{2,2} \end{bmatrix} & A &= \begin{bmatrix} a_{1,1} & a_{1,2} \\ a_{2,1} & a_{2,2} \end{bmatrix} \\
S^{-1} &= \begin{bmatrix} s_{2,2} & -s_{1,2} \\ -s_{2,1} & s_{1,1} \end{bmatrix}
\end{aligned} \tag{39}$$

We then have

$$\begin{aligned}
S^{-1}.A &= S^{-1}A(S^{-1})^T \\
&= \begin{bmatrix} a_{1,1}s_{2,2}^2 - 2a_{1,2}s_{1,2}s_{2,2} & -a_{1,1}s_{2,1}s_{2,2} + a_{1,2}s_{1,1}s_{2,2} \\ +a_{2,2}s_{1,2}^2 & +a_{1,2}s_{1,2}s_{2,1} - a_{2,2}s_{1,1}s_{1,2} \\ -a_{1,1}s_{2,1}s_{2,2} + a_{1,2}s_{1,1}s_{2,2} & a_{1,1}s_{2,1}^2 - 2a_{1,2}s_{1,1}s_{2,1} \\ +a_{1,2}s_{1,2}s_{2,1} - a_{2,2}s_{1,1}s_{1,2} & +a_{2,2}s_{1,1}^2 \end{bmatrix}
\end{aligned} \tag{40}$$

Notice that we also have

$$\begin{aligned} \det \left( \frac{\partial}{\partial S} \right)^n &= \left( \frac{\partial}{\partial S_{1,1}} \frac{\partial}{\partial S_{2,2}} - \frac{\partial}{\partial S_{1,2}} \frac{\partial}{\partial S_{2,1}} \right)^n \\ &= \sum_{k=0}^n (-1)^k \binom{n}{k} \frac{\partial^{n-k}}{\partial S_{1,1}} \frac{\partial^k}{\partial S_{1,2}} \frac{\partial^k}{\partial S_{2,1}} \frac{\partial^{n-k}}{\partial S_{2,2}} \end{aligned} \quad (41)$$

It is quite cumbersome to calculate the Reynolds Operator of general polynomials. We will look at the monomial  $A_{1,1}^2$ , for which we have

$$\begin{aligned} \bar{\mu}'(A_{1,1}^2) &= S_{2,2}^4 \otimes A_{1,1}^2 - 4S_{1,2}S_{2,2}^3 \otimes A_{1,1}A_{1,2} + 2S_{1,2}^2S_{2,2}^2 \otimes A_{1,1}A_{2,2} \\ &\quad + 4S_{1,2}^2S_{2,2}^2 \otimes A_{1,2}^2 - 4S_{1,2}^3S_{2,2} \otimes A_{1,2}A_{2,2} + S_{1,2}^4 \otimes A_{2,2}^2 \end{aligned} \quad (42)$$

We can now apply the Reynolds operator in the way we discussed it in proposition 3.19 in combination with Cayley's  $\Omega$ -process. Since all terms in  $K[\text{SL}_2]$  are already of degree 2, we apply the same to each summand and calculate:

$$\begin{aligned} &R_G \cdot A_{1,1}^2 \\ &= \left( \frac{\partial^2}{\partial S_{1,1}} \frac{\partial^2}{\partial S_{2,2}} - 2 \frac{\partial}{\partial S_{1,1}} \frac{\partial}{\partial S_{1,2}} \frac{\partial}{\partial S_{2,1}} \frac{\partial}{\partial S_{2,2}} + \frac{\partial^2}{\partial S_{1,2}} \frac{\partial^2}{\partial S_{2,1}} \right) \cdot A_{1,1}^2 \\ &= 0 \end{aligned} \quad (43)$$

The zero-polynomial is a trivial invariant, so we see that applying the Reynolds Operator to a polynomial will not always produce interesting results. We will try again for the polynomial  $A_{1,2}^2$ . We calculate

$$\begin{aligned} \mu'(A_{1,2}^2) &= S_{2,1}^2S_{2,2}^2 \otimes A_{1,1}^2 - 2S_{1,1}S_{2,1}S_{2,2}^2 \otimes A_{1,1}A_{1,2} \\ &\quad - 2S_{1,2}S_{2,1}^2S_{2,2} \otimes A_{1,2}^2 + 2S_{1,1}S_{1,2}S_{2,1}S_{2,2} \otimes A_{1,1}A_{2,2} \\ &\quad + S_{1,1}^2S_{2,2}^2 \otimes A_{1,2}^2 + 2S_{1,1}S_{1,2}S_{2,1}S_{2,2} \otimes A_{1,2}^2 \\ &\quad - 2S_{1,1}^2S_{1,2}S_{2,2} \otimes A_{1,2}A_{2,2} + S_{1,2}^2S_{2,1}^2 \otimes A_{1,2}^2 \\ &\quad - 2S_{1,1}S_{1,2}^2S_{2,1} \otimes A_{1,2}A_{2,2} + S_{1,1}^2S_{1,2}^2 \otimes A_{2,2}^2 \end{aligned} \quad (44)$$

Again, all  $K[\text{SL}_2]$  terms are of degree 2, therefore we can simplify and calculate

$$\begin{aligned} &R_G \cdot A_{1,2}^2 \\ &= \left( \frac{\partial^2}{\partial S_{1,1}} \frac{\partial^2}{\partial S_{2,2}} - 2 \frac{\partial}{\partial S_{1,1}} \frac{\partial}{\partial S_{1,2}} \frac{\partial}{\partial S_{2,1}} \frac{\partial}{\partial S_{2,2}} + \frac{\partial^2}{\partial S_{1,2}} \frac{\partial^2}{\partial S_{2,1}} \right) \cdot A_{1,2}^2 \\ &= -\frac{4}{12}A_{1,1}A_{2,2} + \frac{4}{12}A_{1,2}^2 - \frac{4}{12}A_{1,2}^2 + \frac{4}{12}A_{1,2}^2 \\ &= -\frac{1}{3}\det(A) \end{aligned} \quad (45)$$

This is in line with what we expect:  $K[V]^{\text{SL}_n} = K[\det(A)]$ .

## 5 Further Discussion

### 5.1 A Complete Algorithm for Retrieving Generators of the Invariant Ring

Our motivation for having a construction of the Reynolds operator was to not only see that  $\mathrm{GL}_n$  is linearly reductive, but also to yield some invariants. It would also be very helpful if we could somehow produce a generating set for the invariant ring.

In example 4.5, we saw that applying the Reynolds operator to any polynomial does not always result in retrieving a nonzero invariant. It suggests that we somehow need to find the “correct” polynomials to apply the Reynolds operator to. The following proposition (see [DK15, prop. 4.1.1]) gives us exactly that.

**Proposition 5.1**

Let  $V$  be a rational  $G$ -representation where  $G$  is linearly reductive, and let  $I_{>0}$  denote the ideal generated by all non-constant invariants. If  $I_{>0} = (\{f_i\}_{i \in [r]})$  for some homogeneous polynomials  $\{f_i\}_{i \in [r]} \subseteq K[V]$ , we have  $I_{>0} = (\{R(f_i)\}_{i \in [r]})$  and  $K[V]^G = K[\{R(f_i)\}_{i \in [r]}]$ .

In the proof of Hilbert’s finiteness theorem (3.9), we made use of the existence of a finite set of invariants generating  $I_{>0}$ , which was non-constructively given. The previous proposition looks helpful since we have a construction for the Reynolds operator for  $G = \mathrm{GL}_n$  via Cayley’s  $\Omega$ -process, but the problem still remains that we need to have a finite set of homogeneous polynomials generating  $I_{>0}$ , whose existence is here also non-constructively given.

It is in fact possible to compute them with Groebner bases, which is extensively described in [DK15, Algorithm 4.1.9]. This gives us a complete algorithm that takes as its input all of the information necessary to describe our rational representation, which can all be given in terms of polynomials, and outputs a list of generators of the invariant ring.

### 5.2 Cross Ratio

In examples 3.11.1 and 3.13.1 we discussed the cross ratio. Our setting was affine and in  $K^2$ , which makes our results different from the projective setting, where there are not very many other polynomials other than the cross ratio. Using the same conventions and definitions as in the aforementioned examples, we can define the projective cross ratio:

$$\begin{aligned} \text{cr}: \quad Y &\longrightarrow K \\ ([x_1], [x_2], [x_3], [x_4]) &\longmapsto \frac{\det(x_1, x_2) \det(x_3, x_4)}{\det(x_2, x_3) \det(x_4, x_1)} \end{aligned} \quad (46)$$

where  $Y \subseteq P(K^2)^4$  is the set of all pairwise distinct four-tuples of points in  $P(K^2)$ . It should be clear that this is well-defined. The action of  $\mathrm{GL}_2$  on  $X$  induces an action of  $\mathrm{PGL}_n$  on  $Y$ .

Let  $f: Y \rightarrow K$  be an invariant regular function. If  $X_1, X_2, X_3, Y_1, Y_2, Y_3 \in P(K^2)$  with  $X_1, X_2$  and  $X_3$  pairwise distinct and  $Y_1, Y_2$  and  $Y_3$  pairwise distinct, then an important theorem in projective geometry is that there exists a (unique) projective transformation  $\rho \in \text{PGL}(K^2)$  such that  $\rho(X_1) = Y_1$ ,  $\rho(X_2) = Y_2$  and  $\rho(X_3) = Y_3$  (see [Aud03, prop 5.6]). Let  $A, B, C, D \in Y$ , which implies that  $B, C, D$  are pairwise distinct. For  $x \in K$  we define  $x_P := \begin{bmatrix} x \\ 1 \end{bmatrix}$  and  $\infty_P := \begin{bmatrix} 1 \\ 0 \end{bmatrix}$ . There then exists a  $\rho \in \text{PGL}(K^2)$  such that  $\rho(B) = 0_P$ ,  $\rho(C) = 1_P$  and  $\rho(D) = \infty_P$ . Since  $A$  is distinct from  $D$  we know  $\rho(A) \neq \infty_P$ , and therefore there exists some  $a \in K$  such that  $\rho(A) = \begin{bmatrix} a \\ 1 \end{bmatrix}$ . We then compute

$$\begin{aligned} \rho(A) &= \begin{bmatrix} a \\ 1 \end{bmatrix} \\ &= \text{cr} \left( \begin{bmatrix} a \\ 1 \end{bmatrix}, \begin{bmatrix} 0 \\ 1 \end{bmatrix}, \begin{bmatrix} 1 \\ 1 \end{bmatrix}, \begin{bmatrix} 1 \\ 0 \end{bmatrix} \right)_P \\ &= \text{cr}(\rho(A), \rho(B), \rho(C), \rho(D))_P = \text{cr}(A, B, C, D)_P \end{aligned} \tag{47}$$

We then have

$$\begin{aligned} f(A, B, C, D) &= \rho^{-1}.f(A, B, C, D) \\ &= f(\rho(A), \rho(B), \rho(C), \rho(D)) \\ &= f(\text{cr}(A, B, C, D)_P, 0_P, 1_P, \infty_P) \end{aligned} \tag{48}$$

This shows that in the projective setting, there don't exist many more invariants than the cross ratio.

In our affine setting, it suggests that we can transfer the idea, which would mean that  $K[\text{cr}, p(\begin{pmatrix} \text{cr} \\ 1 \end{pmatrix}, \begin{pmatrix} 0 \\ 1 \end{pmatrix}, \begin{pmatrix} 1 \\ 1 \end{pmatrix}, \begin{pmatrix} 1 \\ 0 \end{pmatrix})^{-1}] = K[\text{cr}, (\text{cr}(\text{cr} - 1))^{-1}] = K[\text{cr}, \text{cr}(X_1, X_3, X_4, X_2)]$  are all invariants. This is not true though, since for instance  $\frac{\det(X_1, X_2)}{\det(X_3, X_4)} \in K[X]^{\text{GL}_2}$  is an invariant not included in  $K[\text{cr}, \text{cr}(X_1, X_3, X_4, X_2)]$ .
